## Diagnosis of CTEPH

A normal *V/Q* scan effectively excludes CTEPH with a sensitivity of 90–100% and a specificity of 94–100% [39, 40]. In a study of confirmed cases of CTEPH, *V/Q* scan was found to be superior to CTPA with a sensitivity of 97.4% *versus* 51% [39]. This difference has narrowed as CT technology and interpretation have advanced. Indeed, a more recent study has shown that both *V/Q* scan and CTPA are accurate methods for the detection of CTEPH with excellent diagnostic efficacy (100% sensitivity, 93.7% specificity and 96.5% accuracy for *V/Q* scan; 96.1% sensitivity, 95.2% specificity and 95.6% accuracy for CTPA) [40]. However encouraging, *V/Q* scan remains the preferred initial imaging test for CTEPH screening [5, 29].

Digital subtraction angiography (DSA) had been considered the gold standard for characterising vessel morphology in CTEPH, but is being challenged by advances in non-invasive modalities. CTPA is currently widely used for assessment of operability. CTPA in more recent reports has a high sensitivity and specificity in detecting chronic thromboembolic lesions at the main/lobar (89–100% and 95–100%, respectively) and segmental (84–100% and 92–99%, respectively) levels [43–45]. CTPA can also be

# Pulmonary hypertension in chronic lung disease and hypoxia

## Specific aspects of PH in systemic sclerosis

PH in patients with systemic sclerosis (SSc) can be multifactorial. These patients are at high risk of developing isolated PAH, but they may also develop significant parenchymal lung disease and/or a component of left heart disease. There is often difficulty in discriminating group 1 PAH from group 3 PH in SSc patients, since quite commonly these patients have evidence of parenchymal lung disease on high-resolution CT, which may or may not be accompanied by restrictive physiology. SSc patients with combined pulmonary fibrosis and PH have a particularly high mortality risk [72]. Both PH severity and the extent of pulmonary fibrosis can vary widely. Patients with pre-capillary PH and mild fibrosis are usually classified as having PAH, and have been included in most of the RCTs of PAH medications. However, assessment of the degree of fibrosis was usually based on pulmonary function testing and not scrutiny of the extent of fibrosis on high-resolution CT. Patients with preserved lung volumes can be safely treated with PAH drugs, but there is no evidence for treatment of PH-SSc with more advanced ILD.

- C2 had pre-capillary PH due to extensive ILD and worse 3-year survival compared to C1 (p=0,0004)
- The presence of an extensive ILD, whatever the hemodynamics, is associated with a very severe outcome
- The presence of a limited ILD (often seen as a potent cofounder the classification of PH in tne context of SSc) has to be considered in the same group of patients with no ILD, where the severity of hemodynamics drives the prognosis

# Prognostic significance of computed tomography criteria for pulmonary veno-occlusive disease in systemic sclerosis-pulmonary arterial hypertension

**Michelle J. Connolly[1], Sharif Abdullah[2], Deborah A. Ridout[3], Benjamin E. Schreiber[1], Jamanda A. Haddock[2] and J. Gerry Coghlan[1]**

## Abstract

**Objectives.** SSc-pulmonary arterial hypertension (SSc-PAH) is associated with worse response to therapy and survival when compared with idiopathic PAH. It is suggested that the vasculopathy in SSc may involve postcapillary pulmonary venules resulting in pulmonary veno-occlusive disease (PVOD). This may underlie the lower gas transfer and worse outcome on therapy. We sought to test whether CT signs of PVOD (CTS-PVOD) were frequent in SSc-PAH and whether they were associated with pulmonary oedema on therapy and worse survival.

**Methods.** CT thorax of 66 SSc patients with precapillary pulmonary hypertension (PH) were blindly scored by two radiologists for CTS-PVOD ($\leqslant 1$ or $\geqslant 2$). Case note and radiograph review determined the presence of pulmonary oedema on therapy.

**Results.** Fifty-nine patients (89%) had $\leqslant 1$ CTS-PVOD and only 7 (11%) had $\geqslant 2$ CTS-PVOD. Pulmonary oedema on therapy was relatively common in those with $\geqslant 2$ CTS-PVOD. On univariate analysis $\geqslant 2$ CTS-PVOD were associated with a trend towards worse survival.

**Conclusion.** CTS-PVOD were less frequent in this SSc-PAH cohort than in previous reports but the presence of at least two of these signs is associated with pulmonary oedema on therapy and a trend towards worse survival on univariate analysis.

**Key words:** systemic sclerosis, pulmonary arterial hypertension, computed tomography, systemic sclerosis-pulmonary arterial hypertension, pulmonary veno-occlusive disease

**Fig. 1** Effect of number of CT features of pulmonary veno-occlusive disease on survival

Seminars in Respiratory and Critical Care Medicine Vol. 38 No. 4/2017

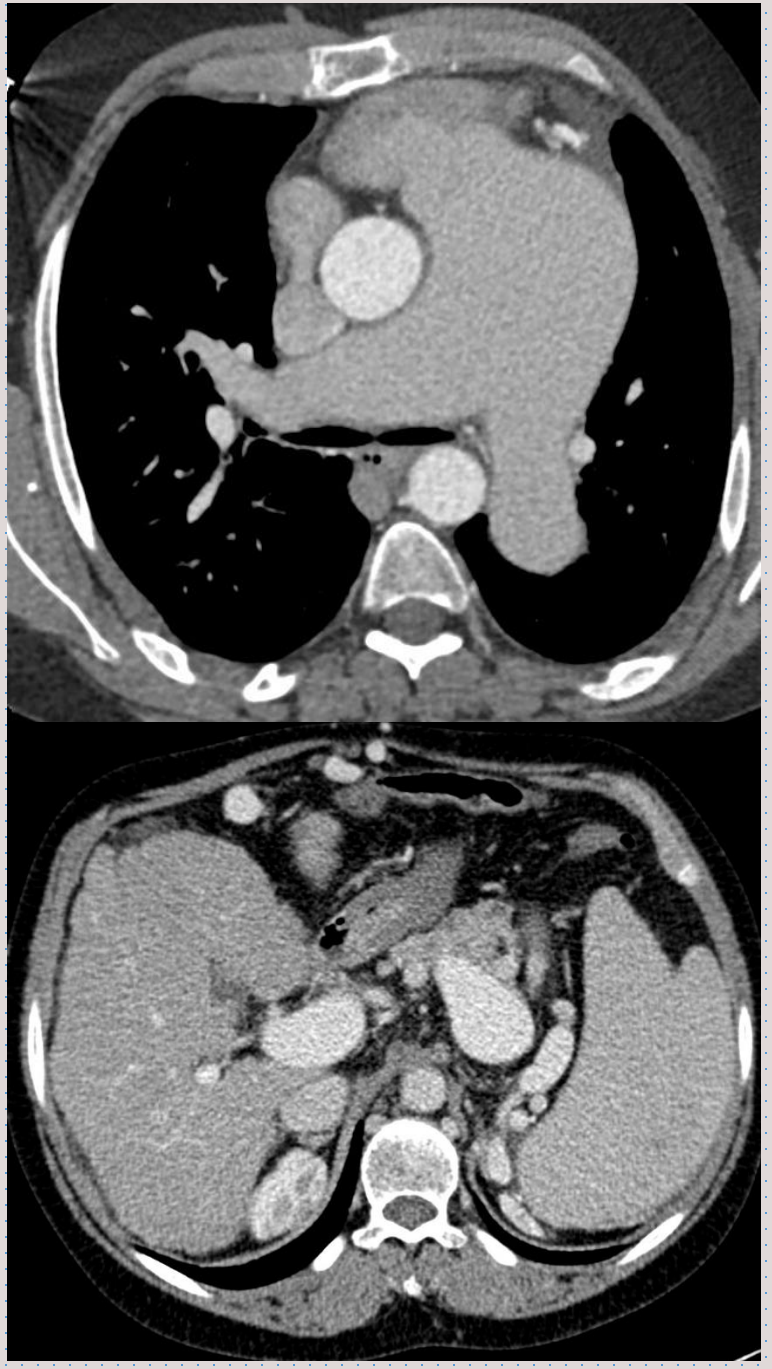
# PoPH: Portal Hypertension

- mPAP ≥ 25 mmHg
- PAWP ≤ 15 mmHg
- PVR > 240 dyne o > 3 Wood units

In presence of portal hypertension confirmed by HPVG > 5 mmHg

Or suggested by the presence of:

- Splenomegaly
- Oesophageal varices
- Thrombocytopenia
- Clinical signs of portosystemic shunt



# Group 5: Tumoral pulmonary hypertension

Eur Respir Rev 2019; 28: 180065 Laura C. Price[1], Michael J. Seckl[2], Peter Dorfmüller[3,4] and S. John Wort[1]

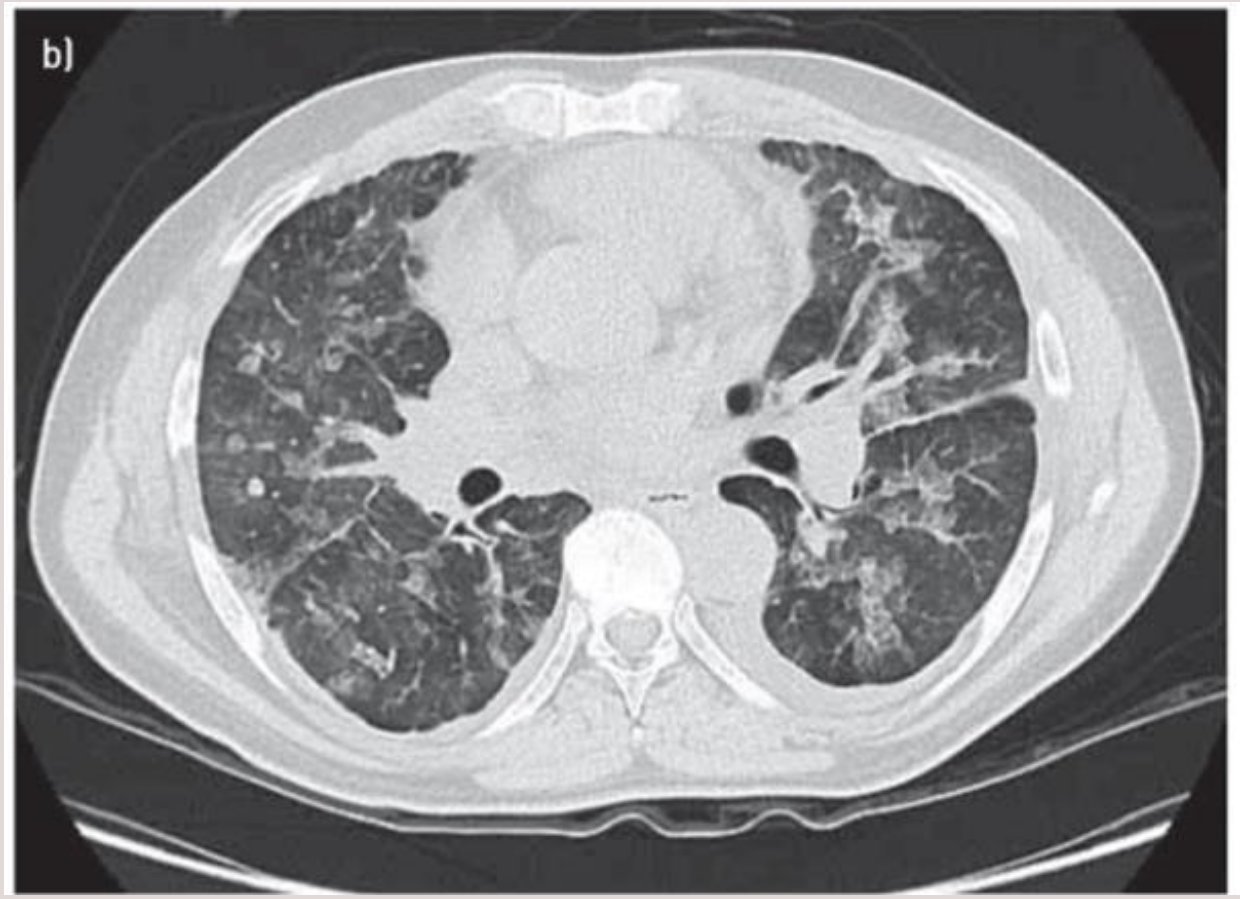
Tumoral pulmonary hypertension (PH) comprises a variety of subtypes in patients with a current or previous malignancy:

- Pulmonary tumour **"microvascular disease"** includes:
  - pulmonary tumour microembolism (PTE)
  - pulmonary tumour thrombotic microangiopathy (PTTM).
- The complications of cancer treatments including: **chemotherapy and radiotherapy** as contributors to PH are increasingly recognised, including cancer treatment-related pulmonary veno-occlusive disease (PVOD)

**5. Pulmonary hypertension with unclear and/or multifactorial mechanisms**

5.1 Haematological disorders: chronic haemolytic anaemia, myeloproliferative disorders, splenectomy
5.2 Systemic disorders: sarcoidosis, pulmonary histiocytosis, lymphangioleiomyomatosis, neurofibromatosis
5.3 Metabolic disorders: glycogen storage disease, Gaucher disease, thyroid disorders
5.4 Others: pulmonary tumoral thrombothic microangiopathy, fibrosing mediastinitis, chronic renal failure (with/without dialysis), segmental pulmonary hypertension

European Heart Journal (2016) 37, 67–119
doi:10.1093/eurheartj/ehv31



Eur Respir Rev 2019; 28: 180065

**PTTM and HRCT**: CT signs of PH and parenchymal abnormalities:

- **Centrilobular nodularity** (The nodularity is usually of an ultrafine granular appearance and is likely to represent the peripheral pulmonary arterial lesions-vascular tree in bud)
- **Ground-glass opacities** (often patchy or wedged shaped)
- **Interlobular septal thickening** (smooth and peripheral in distribution)
- Usually without pleural effusions
- Distinguishing PTTM from lymphangitis carcinomatosis may be difficult and of course these conditions may coexist, but **lymphangitic carcinomatosis does not usually cause significant PH in isolation**
