Severe Aortic Stenosis: Therapy

Indications for transcatheter aortic valve implantation

	Class	Level
TAVI should only be undertaken with a multidisciplinary “heart team” including cardiologists and cardiac surgeons and other specialists if necessary.	I	C
TAVI should only be performed in hospitals with cardiac surgery on-site.	I	C
TAVI is indicated in patients with severe symptomatic AS who are not suitable for AVR as assessed by a “heart team” and who are likely to gain improvement in their quality of life and to have a life expectancy of more than 1 year after consideration of their comorbidities.	I	B
TAVI should be considered in high risk patients with severe symptomatic AS who may still be suitable for surgery, but in whom TAVI is favoured by a “heart team” based on the individual risk profile and anatomic suitability.	Ila	B

« At the present stage, TAVI should not be performed in patients at intermediate risk for surgery and trials are required in this population. »

MACCE

Conclusions

This multicentre study demonstrates that TAVI with the 18-Fr CoreValve ReValving System is associated with sustained clinical and functional cardiovascular benefits in high-risk patients with symptomatic AS up to 3-year follow-up. Non-cardiac causes accounted for the majority of deaths at follow-up.

Cause of death after transcatheter aortic valve implantation.
