Pharmacological Treatment of Heart Failure

- Simplistic Assumptions:
  - All HF is the same
  - HF remains the same for each patient throughout natural history
  - Drugs metabolised on a similar fashion by all
  - Clinical Trial Dose is appropriate for each patient

Baseline characteristics

An MRA is recommended for all patients with persisting symptoms (NYHA class II–IV) and an EF ≤35%, despite treatment with an ACE inhibitor (or an ARB if an ACE inhibitor is not tolerated) and a beta-blocker, to reduce the risk of HF hospitalization and the risk of premature death.	I	A

Predictors for Restoration of Normal Left Ventricular Function in Response to Cardiac Resynchronization Therapy Measured at Time of Implantation

Laura Vitali Serdoz, MD[a], Elisabetta Daleffe, MD[b], Marco Merlo, MD[a], Massimo Zecchin, MD[a], Giulia Barbati, PhD[c], Domenico Pecora, MD[d], Bruno Pinamonti, MD[a], Cecilia Fantoni, MD, PhD[b], Pierpaolo Lupo, MD[b], Andrea Di Lenarda, MD[a], Gianfranco Sinagra, MD, FESC[a], and Riccardo Cappato, MD[b,*]

There are no parameters predicting the individual probability of "full response" to cardiac resynchronization therapy (CRT). The aim of this work was to find prognostic factors of full clinical and echocardiographic responses (i.e., ≥50% left ventricular ejection fraction [LVEF] and New York Heart Association class I) after 1 year of CRT. This was a prospective follow-up study that involved 2 hospitals. Patients (n = 75) with advanced heart failure (64 ± 9 years of age, 87% men, LVEF 24 ± 7%) who received CRT were followed for 17 ± 9 months. Univariate and multivariate regression analyses were used to identify predictors of full CRT response. A nomogram predicting the individual probability of full CRT response during follow-up was calculated. There were 13 patients with restoration of normal LVEF versus 62 without (mean LVEF 56% ± 5% vs 31% ± 8%, respectively, p <0.001). Predictors of full response included cause of heart disease, baseline QRS width, and degree of QRS shortening in response to CRT. Patients with nonischemic heart disease, baseline QRS width ≤150 ms, and QRS shortening ≥40 ms in response to CRT had a >75% probability of restoration of normal LVEF. In conclusion, our nomogram using a combination of cause, baseline QRS width, and degree of QRS shortening in response to CRT allows assessment of individual probability of full response. This observation awaits further confirmation from larger series. (Am J Cardiol 2011;108:75–80)

Prevention of Atrial Fibrillation by Bucindolol Is Dependent on the Beta$_1$389 Arg/Gly Adrenergic Receptor Polymorphism

Ryan G. Aleong, MD,* William H. Sauer, MD,* Gordon Davis, MS,† Guinevere A. Murphy, PHD,† J. David Port, PHD,†‡ Inder S. Anand, MD,§ Mona Fiuzat, PHARMD,|| Christopher M. O'Connor, MD,|| William T. Abraham, MD,¶ Stephen B. Liggett, MD,# Michael R. Bristow, MD, PHD†‡||
Denver and Broomfield, Colorado; Durham, North Carolina; Columbus, Ohio; and Tampa, Florida

Conclusions

Bucindolol was associated with a significant, quantitatively large decrease in new-onset AF in the entire BEST cohort that was observed exclusively in the $\beta_1$389 Arg/Arg genotype.

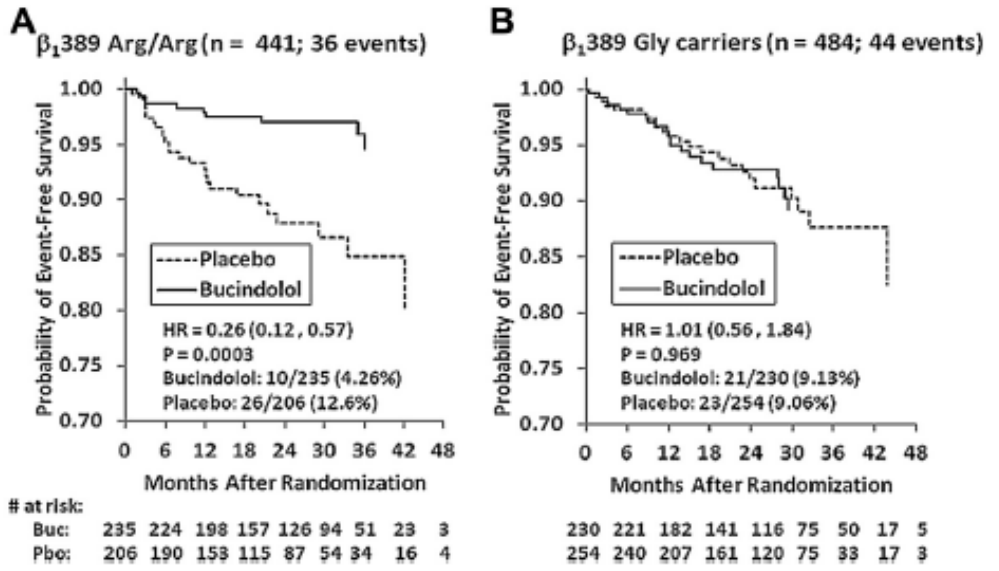

Figure 2 Time to New Onset by $\beta_1$389 Arg/Gly Genotype

Time to event curves are shown for new-onset AF in the BEST DNA substudy by $\beta_1$389 Arg/Gly genotype. There is a significant interaction between genotype and treatment. The benefit of bucindolol is seen exclusively in the $\beta_1$389 Arg/Arg genotype **(A)**, with a risk reduction of 74% compared to placebo ($p = 0.008$ for interaction vs. Gly carrier group). **(B)** There was no impact of bucindolol in the β1 Gly carriers compared to placebo. **Dashed line** = placebo; **solid line** = bucindolol. Abbreviations as in Figure 1.

Heart Regeneration in Zebrafish

Kenneth D. Poss,* Lindsay G. Wilson, Mark T. Keating*

Cardiac injury in mammals and amphibians typically leads to scarring, with minimal regeneration of heart muscle. Here, we demonstrate histologically that zebrafish fully regenerate hearts within 2 months of 20% ventricular resection. Regeneration occurs through robust proliferation of cardiomyocytes localized at the leading epicardial edge of the new myocardium. The hearts of zebrafish with mutations in the Mps1 mitotic checkpoint kinase, a critical cell cycle regulator, failed to regenerate and formed scars. Thus, injury-induced cardiomyocyte proliferation in zebrafish can overcome scar formation, allowing cardiac muscle regeneration. These findings indicate that zebrafish will be useful for genetically dissecting the molecular mechanisms of cardiac regeneration.

Cardiac Cell Therapy — Mixed Results from Mixed Cells

Anthony Rosenzweig, M.D.

Trial or Investigator Group	Setting	Design	No. of Cells Administered in Treatment Group	Results
BOOST[4,9]	PCI after acute myocardial infarction	Randomized trial 30 patients received BMC; 30 received no infusion LVEF assessed by MRI	Approximately 2.5×10^9 unfractionated BMC	At 6 mo: LVEF 6% greater in BMC group than in control group At 18 mo: no significant difference in LVEF between the 2 groups
Janssens et al.[8]	PCI after acute myocardial infarction	Randomized, double-blind trial 33 patients received BMC; 34 received placebo infusion LVEF was assessed by MRI	Approximately 3×10^8 Ficoll-separated BMC	At 4 mo: no significant difference in overall LVEF; decreased infarct size and better regional function in BMC group
TOPCARE-CHD[6]	Chronic left ventricular dysfunction	Randomized, crossover trial In the second phase, 24 patients received CPC, 28 received BMC, 23 received no infusion LVEF assessed by left ventricular angiography	Approximately 2×10^8 Ficoll-separated BMC or approximately 2×10^7 Ficoll-separated, cultured CPC	At 3 mo: greater increase in LVEF (2.9 percentage points) in BMC group than in CPC group or control group
ASTAMI[7]	PCI after acute myocardial infarction	Randomized trial 47 patients received BMC; 50 received no infusion LVEF assessed by SPECT, echocardiography, and MRI	Approximately 7×10^7 Ficoll-separated BMC	At 6 mo: no significant difference in LVEF between the 2 groups
REPAIR-AMI[5]	PCI after acute myocardial infarction	Randomized, double-blind trial 101 patients received BMC; 98 received placebo infusion LVEF assessed by left ventricular angiography	Approximately 2.4×10^8 Ficoll-separated BMC	At 4 mo: greater absolute increase in LVEF in BMC group than in placebo group (5.5% vs. 3.0%) At 1 yr: reduction in combined adverse clinical events in BMC group as compared with placebo group
